

## 4. B) Interfaces

⇒ An interface in Java is a collection of abstract methods that define a set of rules a ~~class~~ class must follow.

● Can have :-

- (i) ~~Only~~ Only Abstract methods
  - All methods are public abstract (by default)
- (ii) Only constants
  - All fields are public static final (by default)

(iii) No Constructors X X

(iv) No method bodies X X

(v) No instance variables X X

(vi) Can extend multiple interfaces

(vii) A class can implement multiple interfaces

(viii) Cannot be instantiated X X

### (i) Interface Syntax

```
interface InterfaceName {  
    // Constant (implicitly public static final)
```

```
    int SOME_CONSTANT = 10;
```

```
    // Abstract method (implicitly public abstract)
```

```
    void method1();
```

```
    int method2(int param);
```

```
}
```

## (ii) Implementing an Interface

```
class ImplementingClass implements InterfaceName {
```

```
// Must implement ALL interface methods
```

```
@Override
```

```
public void method1() {
```

```
// implementation code
```

```
}
```

```
@Override
```

```
public int method2(int param) {
```

```
// implementation code here
```

```
return param * 2;
```

```
}
```

```
}
```

## (iii) Key Points and Rules.

1. Declared with the interface keyword.
2. All interface methods are implicitly public abstract (no private, static, or final methods pre-Java 8).
3. All fields are implicitly public static final constants.
4. No constructor allowed.
5. A class can implement multiple interfaces using comma separation.
6. Classes must implement all methods of their interfaces or declare themselves abstract.
7. Interfaces can extend multiple interfaces simultaneously, e.g.,  
interface C extends A, B { ... }
8. Cannot instantiate interfaces directly { new InterfaceName() } is illegal.
9. Interfaces are for defining capabilities/contracts, separate from implementation.

#### (iv) Interface Reference Variable

- You can declare variables of interface type and assign them instances of implementing class -

ex →

```
InterfaceName obj = new ImplementingClass();  
obj.method1();  
---  
---
```

(Examples, is in Github practice folder)
